Representative Agent Hypothesis & Agent-based Modeling

Background: RAH vs. ABM
What is the Representative Agent Hypothesis?

- The representative-agent hypothesis is a hypothesis in which all agents behave in such a way that their collective actions are assuming to be the actions of one agent making an optimal decision.
- The representative-agent hypothesis allows for greater ease in solution procedures.
  - It is easier to find the equilibrium (relatively...).
  - This is usually called the **analytical optimization** .

Representative Agent Hypothesis & Agent-based Modeling

Background: RAH vs. ABM
What is the Representative Agent Hypothesis?

- **Examples of the representative-agent models:**
  - Profit maximization, utility maximization, or cost/loss minimization...
- **Methods of optimization:**
  - (1) First-order condition - unconstrained optimization
  - (2) Lagrangian multiplier - constrained optimization
  - (3) Dynamic optimization
    - (a) Bellman equation (over discrete time), and
    - (b) Hamiltonian multiplier (over continuous time).

Representative Agent Hypothesis & Agent-based Modeling

Background: RAH vs. ABM
What is Agent-based Modeling?

- Agent-based modeling has been considered as a bottom-up approach modeling behaviors of a group of agents, rather than a representative agent, in a system.
- LeBaron and Tesfatsion (2008, 246): "Potentially important real-world factors such as subsistence needs, incomplete markets, imperfect competition, inside money, strategic behavioral interactions, and open-ended learning that tremendously complicate analytical formulations are typically not incorporated"

Representative Agent Hypothesis & Agent-based Modeling

Background: RAH vs. ABM
What is Agent-based Modeling?

- One important element of ABM is that it allows the possibility of agents' interactions in micro levels with the assumption of bounded-rationality or imperfect information.
- Given agents' heterogenous characteristics and their interactions at the micro level, we can simulate the system and observe changes in the macro level over time according to the system-simulated data.

Representative Agent Hypothesis & Agent-based Modeling

This Presentation

How can EITM be applied to the research of:

1. agent-based modeling - Genetic Algorithm (Arifovic, 1994), and
2. representative agent modeling (Granato, Guse and Wong, 2008; Granato, Lo and Wong, 2010)?

We will focus on a simple dynamic supply-demand model (also called the **Cobweb Model**) in this presentation.
The Cobweb Model - An Introduction

- It is a classic model which illustrates the dynamic process of prices in **agricultural** markets (Kaldor, 1934).
- Due to a lag between planting and harvesting, farmers cannot adjust the amount of agricultural output immediately to fulfill the demand in the market.
- As a result, farmers make their planting decisions today based on the predicted (or forecasted) price of the agricultural product in the next period.
- If farmers expect the price is high in the next period, they would like to plant more today to make more money tomorrow, and vice versa. (The Law of Supply.)

The Cobweb Model - An Introduction

- Assuming that farmers "forecast" the price in the next period based on the price they observe today, that is, $P_{t+1}^e = P_t$.
- If the current price level P_t is high (and is higher than the equilibrium price P^*, which is assumed to be unknown for the farmers). It can be written as: $P_{t=1} > P^*$.
  - **At time $t = 1$ (today),** farmers would like to plant more today for more output ($Q_{t=2}$) sold at a higher price that they expect to happen in the next period. *(All farmers would do the same.)*
  - **At time $t = 2$ (a year later),** all farmers produced more in period 1. Too much output available now. A "surplus" happens in the market (excess supply). Price drops sharply at $t = 2$. The price now goes below the equilibrium: $P_{t=2} < P^* < P_{t=1}$.

The Cobweb Model - An Introduction

The Cobweb Model - An Introduction

- **Are the farmers happy in period 2? Of course not!**
- **What would the farmers do in period 2?**
  - **When $t = 2$:** Since the today's price is low, they expect the price will also be low at $t = 3$, so they are not motivated to produce and decide to plant less today...
  - **When $t = 3$:** Since all farmers again planted less last period ($t = 2$), the total output level turns out to be very low this time. **Shortage happens!**. *Price jumps up at $t = 3$!*
- **Woh!! What do you think the farmers would do now?**
  - **Now $t = 3$:** They see the price becomes high again, they are motivated to produce more for the next period ($t = 4$). They decide to plant more today...
- This story keeps going...

The Cobweb Model - Graphical Representation

The Cobweb Model - Price Movements
The Cobweb Model - Representative Agent Hypothesis

- Assuming each firm i chooses a production level q_{it} to maximize its expected profit π_{it}^e.
- The cost function for firm i is:

$$C_{it} = aq_{it} + \frac{1}{2}bmq_{it}^2, \text{ where } a, b > 0.$$

- Given the expected price of the good P_t^e at time t, firm i is maximizing the following profit function:

$$\pi_{it}^e = P_t^e q_{it} - C_{it}(q_{it}) = P_t^e q_{it} - aq_{it} - \frac{1}{2}bmq_{it}^2.$$

- The first order condition for each firm i is:

$$P_t^e - a - bmq_{it} = 0 \Rightarrow q_{it} = \frac{P_t^e - a}{bm}.$$

The Cobweb Model - Representative Agent Hypothesis

- Assuming all firms are identical so that $q_{it} = q_t \ \forall i$, the aggregate supply in the market is:

$$Q_t = \sum_{i=1}^{m} q_{it} = mq_t = \frac{P_t^e - a}{b}, \tag{1}$$

where $m =$ number of firms in the market.
- Assuming that the market demand is a linear function:

$$P_t = \gamma - \theta Q_t, \tag{2}$$

where $Q_t = \sum q_{it}$.
- In equilibrium where (1)=(2), we can derive the following law of motion for the price level:

$$\frac{\gamma - P_t}{\theta} = \frac{P^e - a}{b} \Rightarrow P_t = \frac{\gamma b + a\theta}{b} - \frac{\theta}{b}P_t^e.$$

Slide 1

The Cobweb Theorem

- The dynamics of the price level:

$$P_t = \frac{\gamma b + a\theta}{b} - \frac{\theta}{b}P_t^e. \tag{3}$$

  - Cobweb Theorem:
    - the model is stable (convergent) if $\theta/b < 1$, that is, $\theta < b$.
    - However, the model is unstable (divergent) if $\theta > b$.
- Equation (3) suggests that the expected price can affect the actual price in the economy. According to the agricultural economy, if we expected the price is high (that is, P_t^e is high), then P_t will be low, and vice versa.
- Economists usually write equation (3) as the following reduced form:

$$P_t = \alpha + \beta P_t^e.$$

The Cobweb Model - Unstable Case
The Cobweb Model - Unstable Case
Modeling Learning Behavior
What is Genetic Algorithm?

- Does our economy really behave the way we describe in the cobweb model?
- What happens to the Cobweb economy if people/firms behavior differently (based on some alternative assumptions)?
- If we assume all firms are heterogeneous initially and they follow the evolutionary process (genetic algorithm) interacting with each other in the economy, would they end up approaching to the same optimal decision (that is, converging to the same equilibrium)?
- **So what is genetic algorithm?**

Background
Genetic Algorithm - The Learning Mechanism

- The genetic algorithm (GA), developed by John Holland (1970), is considered one of the evolutionary algorithms inspired by natural evolution with a core concept of "survival of the fittest".
- The GA describes the evolutionary process of a population of genetic individuals with heterogeneous beliefs in response to the rules of nature.

ABM: Genetic Algorithm

We introduce Arifovic (1994) as an example to investigate if the macro-level stability condition (the cobweb theorem) is necessary for a stable cobweb economy under GA.

We would also like to see how to apply the genetic algorithm on a simple economic model.

Important terms:

- Genes, Chromosomes, and Populations
  - Chromosomes: Genetic individuals making heterogeneous decisions
  - Genes: Elements of a decision that a genetic individual makes
  - Population: A group of genetic individuals with heterogeneous decisions

ABM: Genetic Algorithm

We introduce Arifovic (1994) as an example to investigate if the macro-level stability condition (the cobweb theorem) is necessary for a stable cobweb economy under GA.

We would also like to see how to apply the genetic algorithm on a simple economic model.

Important terms:

- Reproduction, Mutation, and Crossover
  - Reproduction: An individual chromosome is copied from the previous population to a new population.
  - Mutation: One or more gene within an individual chromosome changes value randomly.
  - Crossover: Two randomly drawn chromosomes exchange parts of their genes.

The Cobweb Theorem & Other Expectations Formations

- Let's revisit the dynamics of the price level:

$$P_t = \frac{\gamma b + a\theta}{b} - \frac{\theta}{b} P_t^e. \qquad (4)$$

- According to Cobweb Theorem, the model is stable (convergent) if $\theta/b < 1$, that is, $\theta < b$. However, the model is unstable (divergent) if $\theta > b$.
- Arifovic discusses three types of expectations formations:
  1. Static expectations (i.e., $P_t^e = P_{t-1}$):
     - The model is stable only if $\theta/b < 1$.
  2. Simple adaptive expectations ($P_t^e = \frac{1}{t}\sum_{s=0}^{t-1} P_s$):
     - The model is stable in both cases (Carlson, 1968).
  3. Least squares learning ($P_t^e = \beta_t P_{t-1}$, β_t = OLS coefficient):
     - The model is stable only if $\theta/b < 1$ (Bray and Savin, 1986).

The Basic GA and Arifovic's New GA Operator

- Arifovic (1994) simulates the cobweb model based on three basic genetic operators in the GA simulations:
    - (1) *reproduction*, (2) *mutation*, and (3) *crossover*.
- She also introduces a new operator, called *election*, in the simulations.
- Election is an operator to "examine" the fitness of newly generated (or offspring) chromosomes and then compare them with their parent chromosomes.

New GA Operator - Arifovic (1991, 1994)

- The Rules of Election:
  - Both offspring chromosomes *are elected* to be in the new population at time $t+1$ if $E_t\left(V\left(C_{it+1}^{offspring}\right)\right) > V\left(C_{it}^{Parent}\right)$.
  - However, if only one new chromosome has a higher fitness value than their parents, the one with lower value will not enter the new population, but one of the parents with a higher values stays in the new population.
  - If both new chromosomes have lower values than their parents $E_t\left(V\left(C_{it+1}^{offspring}\right)\right) < V\left(C_{it}^{Parent}\right)$, they cannot enter but their parents stay in the new population.

Conclusions

- Arifovic (1994) introduces the GA procedure as an alternative learning mechanism.
- This alternative learning mechanism mimics social behavior:
  - imitation, communication, experiment, and examination.
- Arifovic uses the GA simulated data to compare with the data generated in human-subject experiments (Wellford, 1989).
  - In an unstable case of the cobweb model, the divergent patterns *do not* happen under both GA learning and human-subject experiments.
  - Price and quantity fluctuate around the equilibrium in *basic* GA learning and human-subject experiments.

The Complete Cobweb Model

- Recall that the basic Cobweb mode is: $P_t = \frac{\gamma b + a\theta}{b} - \frac{\theta}{b}P_t^e$.
- Assuming that there are other external factors (called w_t) and a stochastic shock (η_t) which can influence the actual price at time t (P_t), we can present the complete Cobweb model as the follows:
$$P_t = \alpha + \beta P_t^e + \gamma w_{t-1} + \eta_t. \tag{5}$$
- Equation (5) has been widely studied in the economic literature since 1960.

The Cobweb Model and Information Diffusion

An Extended Research Question

What would happen to an economy if there exists information interaction among agents?

Answer

The Boomerang Effect: Less-informed agents' forecasts confound those of more-informed agents whenever there is misinterpretation in the information acquisition process. (Granato, Guse and Wong, 2008)

Background
Introduction to the Cobweb Model
Agent-based Modeling
Representative Agent Hypothesis

Motivation - Literature Review

1. **Information Diffusion**
   1. Granato and Krause (2000): inflation forecasts of a better educated group influence the less educated group's forecasts, but *not* vice versa.
   2. Financial Economic: Herding behavior (Devenow and Welch, 1996)

2. **Information Asymmetries**
   - Romer and Romer (2000): The Fed has inflation information superior to that of commercial forecasters;

3. **Heterogeneous Information Interpretation**
   - Kandel and Zilberfarb (1999): People do not interpret the existing information in an identical way.

EITM in Practice

Granato, Lo and Wong (2011) is an empirical study (EI) based on the theoretical framework (TM) in Granato, Guse and Wong (2008) where they explore the equilibrium properties in a modified cobweb model with a process of asymmetric information diffusion.

Things to be tested...

- Asymmetric Information Diffusion:
  - Granger Causality Tests
  - Impulse Response of Innovations
- The Boomerang Effect:
  - Rolling-Window Estimations
  - Cointegration estimation
  - Vector Error Correction (VEC) Granger Causality Tests

Information Diffusion Model: Granato, Lo and Wong (2011)
The Boomerang Effect
Empirical Testing

The Cobweb Model of Inflation Expectations

Using a supply curve and monetary policy, we can derive the reduced-form model of inflation expectations which is consistent with the standard Cobweb model in equation (5):

$$\pi_t = \alpha + \beta E_{t-1}^* \pi_t + \gamma w_{t-1} + \eta_t, \qquad (6)$$

where $\pi_t = p_t - p_{t-1}$, $\alpha = (1+\theta)^{-1}(\kappa + \bar{m} + \bar{y})$, $\beta = \theta(1+\theta)^{-1}$, $\gamma = (1+\theta)^{-1}(\phi + \lambda)$, and $\eta_t = (1+\theta)^{-1}(\varepsilon_t + \varepsilon_t' + \xi_t)$.

Equation (6) is a self-referential model where inflation depends on:

1. its expectations $\left(E_{t-1}^* \pi_t \right)$;
2. exogenous variables (w_{t-1}); and
3. stochastic shocks (η_t)

Inflation Expectations Diffusion Process

The Cobweb model in equation (6) with a process of inflation expectations diffusion:

$$\pi_t = \alpha + \beta E^*_{t-1}\pi_t + \gamma w_{t-1} + \eta_t, \qquad (7)$$

New Assumptions (Granato, Guse and Wong, 2008):

1. Information Asymmetry:
   More-informed group (Group H) vs. Less-informed group (Group L)
2. Information Diffusion:
   Group L makes forecasts by observing Group H's forecasts
3. Heterogeneous Information Interpretation:
   Agents in Group L interpret Group H's forecasts differently

Background

Inflation Expectations Diffusion Process

How? Two groups of representative agents: (1) more-informed agents (Group H); and (2) less-informed agents (Group L).

- Group H's Forecasts:

$$E^*_{H,t-1}\pi_t = a_H + b_{1H}x_{t-1} + b_{2H}z_{t-1}, \qquad (8)$$

- Group L's Forecasts:

$$E^*_{L,t-1}\pi_t = a_L + b_L x_{t-1} + c_L \hat{\pi}_{t-1}, \qquad (9)$$

- where:

$$\hat{\pi}_{t-1} = E^*_{H,t-1}\pi_t + e_{t-1} \text{ (Information Diffusion)}, \qquad (10)$$

$w_{t-1} = [x_{t-1}, z_{t-1}]'$ (Asymmetric Information), and
$e_{t-1} \sim iid\left(0, \sigma^2_e\right)$ is the observation error of observing the expectations of Group H (Heterogeneous Information Interpretation).

Inflation Expectations Diffusion Process

- Assuming that there is a continuum of agents located on the unit interval $[0,1]$ of which a proportion of μ, where $\mu \in [0,1)$ are agents in Group L and $(1-\mu)$ are in Group H.
- Therefore, the expectations of inflation in the market is the weighted average of the expectations from both groups:

$$E^*_{t-1}\pi_t = \mu E^*_{L,t-1}\pi_t + (1-\mu) E^*_{H,t-1}\pi_t \qquad (11)$$

Mixed Expectations Equilibrium (MEE)

The MEE for Group L and Group H:

$$\bar{\varphi}_L = \begin{pmatrix} \bar{a}_L \\ \bar{b}_L \\ \bar{c}_L \end{pmatrix} = \begin{pmatrix} \frac{\alpha}{1-\beta}(1-\bar{c}_L) \\ \frac{\gamma_1}{1-\beta}(1-\bar{c}_L) \\ \frac{\bar{b}_{2H}^2 \sigma_z^2}{\bar{b}_{2H}^2 \sigma_z^2 + (1-\beta\mu)\sigma_e^2} \end{pmatrix} \quad (12)$$

$$\bar{\varphi}_H = \begin{pmatrix} \bar{a}_H \\ \bar{b}_{1H} \\ \bar{b}_{2H} \end{pmatrix} = \begin{pmatrix} \frac{\alpha}{1-\beta} \\ \frac{\gamma_1}{1-\beta} \\ \frac{\gamma_2}{1-\beta+\beta\mu(1-\bar{c}_L)} \end{pmatrix} \quad (13)$$

The Boomerang Effect on Expectations

Group L's observational errors affect Group H's forecast equilibrium:
$$\sigma_e^2 \Rightarrow \bar{b}_{2H}.$$

Forecast Accuracy: Mean Square Errors (MSE)

The Definition of MSE:

$$MSE = E\left(\pi_t - E_{t-1}^* \pi_t\right)^2$$

therefore,

$$MSE_i = E\left(\pi_t - E_{i,t-1}^* \pi_t\right)^2 \text{ for } i \in \{L, H\}$$

Background
Introduction to the Cobweb Model
Agent-based Modeling
Representative Agent Hypothesis
Extras

Information Diffusion Model: Granato, Lo and Wong (2011)
The Boomerang Effect
Empirical Testing

The Boomerang Effect on MSE

MSE for Group L and Group H:

$$MSE_L = \left[\frac{\gamma_2(1-\bar{c}_L)}{1-\beta+\beta(1-\bar{c}_L)\mu}\right]^2 \sigma_z^2 + (1-\beta\mu)^2 \bar{c}_L^2 \sigma_e^2 + \sigma_\eta^2 > \sigma_\eta^2$$

$$MSE_H = (\beta\mu\bar{c}_L)^2 \sigma_e^2 + \sigma_\eta^2 > \sigma_\eta^2$$

The Boomerang Effect on MSE

Group L's observational errors affect Group H's forecast Accuracy:
$$MSE_H > \sigma_\eta^2 \text{ for } \sigma_e^2 > 0.$$

The larger the observation error made by Group L in interpreting
Group H's forecasts (larger σ_e^2), the greater the inaccuracy in
prediction by Group H (MSE_H).

There is a positive relationship between σ_e^2 and MSE_H.

Testing Asymmetric Information Diffusion

Based on Granger causality tests and impulse response of innovations, we find that the less-educated agents observe higher-educated agents in forecasting inflation. There exists the process of asymmetric information diffusion between less- educated and higher-educated groups.

The precondition of the Boomerang Effect is satisfied.

Background
Introduction to the Cobweb Model

Information Diffusion Model: Granato, Lo and Wong (2011)
The Boomerang Effect
Empirical Testing

Testing the Boomerang Effect

Testing the Boomerang Effect

1. Rolling-window estimations of σ_e^2 and MSE_H
2. Cointegration estimation
3. Vector error correction Granger causality tests

Step 1a. Rolling-Window Estimation of σ_e^2

Group H's and L's Forecasts:

$$E_{H,t-1}^* \pi_t = a_H + b_{1H} x_{t-1} + b_{2H} z_{t-1}$$

$$E_{L,t-1}^* \pi_t = a_L + b_L x_{t-1} + c_L \hat{\pi}_{t-1}$$

and

$$\hat{\pi}_{t-1} = E_{H,t-1}^* \pi_t + e_{t-1}$$

Background
Introduction to the Cobweb Model
Agent-based Modeling
Representative Agent Hypothesis
Extras

Information Diffusion Model: Granato, Lo and Wong (2011)
The Boomerang Effect
Empirical Testing

Testing the Boomerang Effect

Therefore:

$$E_{L,t-1} \pi_t = a_{L,t-1} + b_{L,t-1} x_{t-1} + c_{L,t-1} \left(E_{H,t-1} \pi_t + e_{t-1} \right).$$

We have:

$$e_{t-1} = \frac{E_{L,t-1} \pi_t - a_{L,t-1} - b_{L,t-1} x_{t-1} - c_{L,t-1} E_{H,t-1} \pi_t}{c_{L,t-1}}.$$

We can calculate:

$$\sigma_{e_{Lj}}^2 = \frac{\sum_t^{t+s} e_{Lj,t-1}^2}{s-1},$$

for all t and s = size of the rolling window, and $Lj = \{L1, L2\}$.

Background

Agent-based Modeling
Representative Agent Hypothesis
Extras

Information Diffusion Model: Granato, Lo and Wong (2011)
The Boomerang Effect
Empirical Testing

Testing the Boomerang Effect

Step 1b. Rolling-Window Estimation of MSE_H

By definition, MSE_H can be calculated as:

$$MSE_H = \frac{\sum_t^{t+s}(\pi_t - E_{H,t-1}\pi_t)^2}{s}$$

Our primary concern is the long run relation between σ_e^2 and MSE_H.

A larger value of σ_e^2 causes MSE_H to increase.

Concluding Remarks

- A larger value of σ^2_e causes MSE_H to increase.
  - The Boomerang Effect exists in the inflation expectations survey data.
- σ^2_e granger causes MSE_H, but not vice versa.
  - The finding of Boomerang Effect is robust using the inflation expectations survey data.

Profit Maximization

1. Profit function: $\pi = p \times q - c(q)$.
2. Demand: $p = a - bq$.
3. Supply (cost function): $c = d + eq$.
4. Maximizing profit: $\max_q \pi = (a - bq)q - (d + eq)$.
5. Optimal level of output: $q^* = (a - e)/2b$.

A Simple Profit Maximization Problem
The GA Operators
MATLAB Codes
Simulations
Concluding Remarks

Notations under the GA

- Chromosome C_i consists of a set of 0 and 1, where L is the length of a chromosome (the number of genes).
- $B^{max}(C_i) = 2^L - 1$ represents the maximum numerical value of a chromosome with the length L.
  - For example, if $L = 10$, the maximum value of a chromosome:
  $$B(1111111111) = 2^{10} - 1 = 1023.$$
- We can use the B operator to compute a numerical value of a chromosome (e.g., $C_i = 0100101110$) :

$$\begin{aligned} B(0100101110) = {} & 0 \times 2^9 + 1 \times 2^8 + 0 \times 2^7 + 0 \times 2^6 + \\ & 1 \times 2^5 + 0 \times 2^4 + 1 \times 2^3 + 1 \times 2^2 + \\ & 1 \times 2^1 + 0 \times 2^0 = 302. \end{aligned}$$

Concluding Remarks

Notations under the GA

- According to the problem of profit maximization, if $a = 200$, $b = 4$, and $e = 40$, then $q^* = 20$.
- In this case, the maximum value of a chromosome can be too large for this problem ($B^{max} = 1023$).
- We can define a maximum economic value for a chromosomes $V(C_i)$ based on the following value function:

$$V(C_i) = \frac{U^{max}}{B^{max}} \times B(C_i),$$

where $V(C_i) \in [0, U^{max}]$ for $B(C_i) \in [0, B^{max}]$, and U^{max} is the maximum economic value in the problem.

Agent-based Modeling
Representative Agent Hypothesis
Extras

A Simple Profit Maximization Problem
The GA Operators
MATLAB Codes
Simulations
Concluding Remarks

Notations under the GA

- Is firm i doing a good job? We need to evaluate firm i using a fitness function $F(C_i)$.
- The profit function is used as the fitness function in this case:

$$F(C_i) = \pi(V(C_i))$$
$$= \pi(q_i) = (a - bq_i)q_i - (d + eq_i).$$

- In this case,

$$F(C_i) = \pi(V(C_i))$$
$$= \pi(29.52) = (200 - 4(29.52))(29.52) - (50 + 40(29.52))$$
$$= 1187.48.$$

- The maximum profit is (for $q* = 20$):

$$F^{max} = \pi(q^*) = \pi(20) = 1550.$$

The GA Operators
Reproduction $\Rightarrow$ Evolutionary Dynamics

- Reproduction is a genetic operator where an individual chromosome is copied from the previous population to a new population.
- The probability of being drawn for each chromosome is calculated based on the fitness value.
  - Higher fitness value $\Rightarrow$ higher probability of being drawn to the new population.
- The relative fitness function is:

$$R(C_{i,t}) = \frac{F(C_{i,t})}{\sum_{m=1}^{M} F(C_{m,t})},$$

where $\sum_{i \in M} R(C_{i,t}) = 1$.
- The relative fitness value $R(C_{i,t})$ gives us the probability chromosome i is copied to the new population at time $t+1$.

The GA Operators
Reproduction

- What if $F(C_{i,t})$ is negative for some firm i? (a negative profit?)
- Goldberg (1989) proposes a scaled relative fitness function:

$$S(C_{i,t}) = \frac{F(C_{i,t}) + A}{\sum_{m=1}^{M} [F(C_{m,t}) + A]} = \frac{F(C_{i,t}) + A}{\sum_{m=1}^{M} F(C_{m,t}) + MA},$$

where A is a constant such that $A > -\min_{C_i \in P_t} F(C_{i,t})$.

Reproduction $\Rightarrow$ Evolutionary Dynamics

- Reproduction is a genetic operator where an individual chromosome is copied from the previous population to a new population.
- The probability of being drawn for each chromosome is calculated based on the fitness value.
    - Higher fitness value $\Rightarrow$ higher probability of being drawn to the new population.
- The relative fitness function is:

$$
R(C_{i,t}) = \frac{F(C_{i,t})}{\sum_{m=1}^{M} F(C_{m,t})},
$$

where $\sum_{i \in M} R(C_{i,t}) = 1$.
- The relative fitness value $R(C_{i,t})$ gives us the probability chromosome i is copied to the new population at time $t+1$.

The GA Operators
Reproduction

```
122        %This is the code for Reproduction
123 -      norm_fit = SC
124 -      selected = rand(size(SC))
125 -      sum_fit = 0;
126 -      for i=1:length(SC)
127 -          sum_fit = sum_fit + norm_fit(i)
128 -          index = find(selected<sum_fit)
129 -          selected(index) = i*ones(size(index))
130 -      end
131 -      gen = gen(selected,:)
132
```

Goldberg (1989) proposes a scaled relative fitness function:

$$S(C_{i,t}) = \frac{F(C_{i,t}) + A}{\sum_{m=1}^{M} [F(C_{m,t}) + A]} = \frac{F(C_{i,t}) + A}{\sum_{m=1}^{M} F(C_{m,t}) + MA},$$

where A is a constant such that $A > -\min_{C_i \in P_t} F(C_{i,t})$.

The Basic GA Simulations

- Market Parameters:
  - Demand: $a = 200$, and $b = 400$.
  - Supply: $d = 50$, and $e = 40$.
  - Optimal output: $q^* = 20$.

- GA Parameters:
  - $M = 200$ (200 genetic agents)
  - $L = 16$, therefore $B^{max} = 65535$.
  - $U^{max} = 50$ (maximum output $q^{max} = 50$)
  - $\kappa = 0.3$ (probability of crossover)
  - $\mu = 0.0033$ (probability of mutation)
  - $t = 500$ (500 generations)

Concluding Remarks

- Why do we use the GA (or ABM in general) for political science / economics research??
  - Some models are mathematically intractable (we cannot find a closed-form equilibrium).
  - No strong assumptions imposed (such as, efficient markets, rational agents, representative agent hypothesis).
  - It allows non-linearity in a theoretical model.
  - It is relatively easier to capture equilibrium (equilibria) in a multi-national, multi-sector model.

Extra 2: The Setup of Inflation Expectations Model

The Lucas Supply Curve is:

$$y_t = \bar{y} + \theta \left(p_t - E_{t-1}^* p_t \right) + \varepsilon_t \tag{14}$$

and QTM is:

$$m_t + v_t = p_t + y_t, \tag{15}$$

where velocity depends on some exogenous observables (w_{t-1}):

$$v_t = \kappa + \lambda w_{t-1} + \varepsilon_t' \tag{16}$$

and money supply (m_t) is represented as a policy rule:

$$m_t = \bar{m} + \phi w_{t-1} + \xi_t, \tag{17}$$

where $\bar{m}$ is a constant money stock.
